

VeriSight

UX-Focused Identity Verification Platform

Project Report — Axlero Solutions UI/UX Internship

1. Executive Summary

VeriSight is a UX-focused identity verification platform designed to simplify digital onboarding through clear guidance, intuitive interactions, transparent feedback, and a consistent design system while maintaining high security standards. The project was developed as part of the Axlero Solutions UI/UX intern project program.

The project addresses common identity-verification problems such as lengthy processes, unclear instructions, repeated failures, permission-related issues, generic error messages, and low user confidence around privacy and security. The final UX work covers authentication, passkey setup, identity verification, recovery, dashboard, security-status, profile, and settings experiences.

2. Problem Statement

Identity verification is essential for digital banking, fintech, healthcare, government, and other services, but many existing experiences are difficult to complete. Users may encounter unclear instructions, repeated verification failures, permission issues, generic errors, and limited feedback about what is happening.

VeriSight approaches this as a UX problem: security requirements should be communicated clearly, the user should understand each step, and failures should provide a useful recovery path instead of becoming dead ends.

3. Project Objectives

- Simplify identity verification.
- Improve digital-onboarding usability.
- Reduce avoidable verification failures through clearer guidance.
- Provide meaningful feedback at every stage.
- Build user trust through transparent security interactions.
- Create an accessible interface for users with different levels of technical experience.
- Maintain a consistent design system across the application.
- Connect verification with the broader authenticated dashboard experience.

4. Target Users

Primary users include adults aged 18–60, users opening bank or fintech accounts, individuals completing digital KYC verification, and professionals using secure digital identity services. Secondary users include first-time digital users, elderly users, users with limited technical experience, and people who prioritize secure authentication and privacy.

Core needs are a quick and simple process, clear instructions, transparent progress, helpful recovery options, and confidence that personal information is protected.

5. User Persona

Aarav Sharma — 29 — Software Engineer — Bengaluru, India.

Goals: complete verification quickly; keep personal information secure; finish onboarding successfully on the first attempt.

Pain points: repeated verification failures; unclear instructions; poor lighting affecting face detection; generic error messages without a clear solution.

Needs: step-by-step guidance; immediate visual feedback; easy retry options; transparent communication.

6. Design Process

The project followed the documented workflow: **Research** → **User Flow** → **Low-Fidelity Wireframes** → **High-Fidelity UI** → **Prototype**.

The broader process included problem definition, objectives, target-user and persona work, user-flow mapping, design-system definition, high-fidelity UI, interactive Figma prototyping, error-state/recovery design, and final-flow integration.

7. Application Modules

Authentication & Account Setup — Member 1: Splash, Welcome, Login, Sign Up, Forgot Password.

Passkey Setup — Member 2: Passkey Intro, Create Passkey, Face ID/Fingerprint Setup, Passkey Success, Recovery Options.

Identity Verification — Member 3: Camera Permission, face/liveness tasks, verification result and recovery.

Error Handling + Dashboard — Member 4: Permission Denied, Face Not Detected, Poor Lighting, Retry Verification, Help & Support, Dashboard, Security Status, Profile, Settings.

8. Identity Verification Module

The Identity Verification module guides the user through a secure facial/liveness verification experience while keeping the interaction simple and understandable.

Design goals include guiding users through each step, reducing failed attempts, providing continuous feedback, maintaining transparency, offering recovery options, and staying consistent with the project design system.

9. Verification Flow

The current prototype flow is:

Verification Intro → **Camera Permission Overlay** → **Allow** → **Liveness Task 1** → **Task 1 Success** → **Task 2** → **Task 2 Success** → **Task 3** → **Task 3 Success** → **Task 4** → **Task 4 Success** → **Verification Success** → **Dashboard**.

The four guided liveness tasks are: **Smile naturally**, **Give a quick wink**, **Turn the head slightly left**, and **Tilt the head slightly down**. Each task has a success state and progress feedback. The Figma prototype uses timed transitions to simulate detection and completion.

10. Permission & Error Recovery

The prototype covers multiple recovery scenarios.

Camera permission denied: explains why camera access is required and provides a retry path and settings guidance.

Poor lighting: tells the user that the environment needs improvement and allows them to retry.

Face not detected: provides positioning guidance and a retry path.

Verification failure: provides a dedicated failure result and a route back into verification/retry.

11. Result & Dashboard Integration

After the final liveness task, the user receives a clear verification-success result. Continuing from the result takes the user to the dashboard, where verification status is reflected as verified. The dashboard also provides a Start Verification entry point for re-entering the verification journey when required.

12. Design System

Core documented tokens are:

Primary #2563EB **Secondary** #60A5FA **Success** #22C55E **Warning** #F59E0B **Error** #EF4444

Background #EDF3FA **Surface** #FFFFFF **Text Primary** #111827 **Text Secondary** #6B7280 **Border** #E5E7EB

Typography uses SF Pro with Display, Heading 1–3, Body, Body Small, and Caption. The documented spacing scale is 8 / 16 / 24 / 32 px, with 8 / 12 / 16 px small/medium/large radii and defined button/input states.

13. Accessibility Considerations

The project considers accessibility as part of the security flow. VoiceOver can communicate task instructions, progress, success, and errors. Haptic feedback can provide non-visual confirmation for task detection, completion, and error states.

The current deliverable is a Figma UX prototype, so device-level VoiceOver and haptic behavior is an intended implementation consideration rather than a functionally executed hardware/software feature.

14. Tools & Deliverables

Figma was used for wireframes, the design system, high-fidelity UI, and prototype linking. Supporting deliverables include UX documentation, wireframe exports, UI-screen exports, the project report, and the project presentation.

15. Prototype Scope & Limitations

This submission is a UX/UI prototype rather than a production biometric-verification system. The Figma prototype simulates liveness and result states and does not itself perform facial analysis, anti-spoofing, camera processing, cryptographic authentication, or backend identity verification.

Where the project brief describes underlying technical liveness mechanisms, this report treats those as product/UX requirements rather than claiming they are implemented inside Figma.

16. Team Contributions

The project is structured as a four-member team, with each member owning a feature module end-to-end from research through prototype.

Member 1 – Chetana Randhaye: Authentication & Account Setup; Problem Statement & Objectives.

Member 2 – Garima Saxena: Passkey Setup

Member 3 – Vaibhvai Parmar: Identity Verification; User Persona & User Flow.

Member 4 – Harsh Swaroop: Error Handling + Dashboard; Final Documentation, Presentation

18. Conclusion

VeriSight demonstrates a UX approach to identity verification that makes security clearer, more interactive, and more recoverable. The prototype combines guided liveness interactions, permission handling, immediate feedback, explicit result states, and recovery paths within a consistent visual system.

The resulting work provides a UX foundation for a secure FinTech onboarding experience. Future implementation would connect these UX states to actual biometric, passkey, accessibility, privacy, and backend security mechanisms.
